Complex molecular switches have been synthesized by exploiting the reversible reactions of the cyclophane-quinone diimine molecule and its phenyl-derived quinone analog as self-assembled monolayers. The switches were deposited as a single layer on Ag nanowires, forming all-organic molecular

junctions. These structures were characterized with scanning tunneling microscopy, X-ray photoelectron spectroscopy, and cyclic voltammetry. Significant changes in the single molecule conductance, from 10^{-4} to 10^{-1} G₀, were achieved upon modulation of the chemical structure. They are driven by local switching of the chemical environment within the junctions. The following chart depicts account activity as of Sept. 4, 2018.
